Golang Interview Questions by Topic Area

1. Core Language Features

Basic

- **Key Go Features:** What are some of the key features of the Go language that differentiate it from other languages (e.g. open source, compiled, garbage-collected, concurrency support, etc.)? [1] [2]
- **Variables and Declaration:** How do you declare variables in Go? What is the difference between using the `var` keyword and the short declaration `:=` syntax?
- **Multiple Return Values:** Can Go functions return multiple values? Give an example of a function signature that returns two values and explain a use case for multiple returns.
- **Blank Identifier:** What is the purpose of the blank identifier (`_`) in Go, and when would you use it? (For example, to ignore an unused return value or to import a package only for side-effects.)
- **Value vs Reference Semantics:** Are function arguments in Go passed by value or by reference? Explain what this means for types like pointers, slices, maps, and channels.

Intermediate

- **Defer Usage:** What does the `defer` statement do in Go? When are deferred functions executed, and how is this useful for resource management?
- **Init Function:** What is the `init()` function in a Go package? When is it run, and what are some appropriate and inappropriate uses for `init`?
- **Closures and Anonymous Functions:** What is a closure in Go? Provide an example of an anonymous function capturing an external variable, and explain how closures can be useful.
- **Constants and iota:** How do you declare constant values in Go? What is the `iota` identifier and how can it be used to create enumerated constants?
- **Variadic Functions:** What is a variadic function in Go? How do you define a function that accepts a variable number of arguments, and how do you call it?

Advanced

- **Deferred Calls Mechanics:** Explain how deferred function calls work in Go. In what order are multiple deferred calls executed, and when are the deferred function's arguments evaluated? (For example, if you defer a function call with arguments, are those arguments evaluated at defer time or when the function executes?)
- **Reflection:** What is the `reflect` package used for in Go? Describe a scenario where using reflection is necessary, and discuss the downsides of using reflection in terms of type safety and performance.
- **Unsafe Package:** What is the `unsafe` package in Go? Give an example of something that can be done with `unsafe` (such as converting a slice of bytes to a string without copying) and explain why this is not normally allowed by the type system.
- **Loop Variable Capture:** In Go versions before 1.22, what issue could occur when closures capture loop variables, and how would you work around it? (Hint: each iteration of a `for` loop uses the same loop variable, so capturing it in a goroutine can be problematic.)

- **Embedding vs Inheritance:** Go doesn't have traditional class inheritance. How does struct embedding in Go provide an alternative? What happens if two embedded structs have a method with the same name?

2. Data Structures and Memory

Basic

- **Arrays vs Slices:** What are the differences between arrays and slices in Go? How do you declare each, and how does their behavior differ in terms of length, capacity, and mutability?
- **Maps:** How do you declare and initialize a map in Go? Give an example of inserting, retrieving, and deleting an element in a map. What restrictions exist on the types that can be used as map keys (e.g. they must be comparable)? [3] [4]
- **Pointers:** What is a pointer in Go? How do you obtain the address of a variable and dereference a pointer? Provide a simple example of using a pointer to modify a variable's value.
- **Structs:** What is a struct in Go and how do you define one? Illustrate with an example struct type and how to create an instance of it (literally or using `new`). What are struct field tags used for?

Intermediate

- **Slice Capacity and Growth:** Explain the relationship between a slice's length and capacity. What happens under the hood when you append an element to a slice that has reached its capacity? How does Go decide when and how much to grow the underlying array?
- **Nil vs Empty Slices:** What is the difference between a nil slice and an empty slice (`[]T{}`)? How can you check for each, and is there any practical difference in how you use them?
- **Nil Maps:** What is the behavior of a nil map in Go? Can you read from or write to a nil map, and how do you properly initialize a map before use?
- **Map Key Comparability:** Which types can be used as keys in a Go map and why? (For example, why can't you use a slice as a map key?) [3]. What happens if you try to use a struct that contains an uncomparable field as a map key?
- **Pointer vs Value Semantics:** When defining methods on a struct, how do you decide whether to use a pointer receiver or a value receiver? Discuss the implications for memory (e.g. avoiding copies for large structs or needing to mutate the receiver).

Advanced

- **Slice Internals:** Describe how a slice is represented in memory. What information does a `[]T` slice value contain, and how do those fields change when you re-slice or append to a slice?
- **Sub-slice Append Gotcha:** If you create a subslice of a larger slice and then append to the subslice, under what conditions will changes in the subslice affect the original slice? (Discuss slice capacity and when a new underlying array gets allocated.)
- **Map Implementation:** At a high level, how are maps implemented in Go's runtime? (For example, mention hash tables with buckets.) What is the average-time complexity of map lookups and inserts, and what is a worst-case scenario for a map's performance?
- **Escape Analysis:** What is escape analysis in Go? Why does the compiler sometimes decide to allocate variables on the heap rather than the stack [5], and how can you detect when this happens?
- **Struct Alignment:** How does memory alignment and padding affect the size of a struct in Go? If you are trying to reduce a struct's memory footprint, what can you do about field ordering and why does it matter?

3. Concurrency and Goroutines

Basic

- **Goroutines:** What is a goroutine and how do you launch one? How is a goroutine different from an OS thread in terms of cost and scheduling? [6]
- **Channels:** What is a channel in Go and how do you use it for communication between goroutines? Show a simple example of creating a channel, sending a value, and receiving a value.
- **Race Conditions:** What is a race condition in the context of concurrent programming? How can race conditions occur in Go, and how can you avoid them when multiple goroutines access shared data?
- **Sync WaitGroup:** How can you wait for multiple goroutines to finish their work before continuing? Give an example of using a `sync.WaitGroup` to coordinate goroutines.
- **Concurrency vs Parallelism:** What is the difference between concurrency and parallelism? Can Go do parallel execution of goroutines, and if so, what setting controls the degree of parallelism?

Intermediate

- **Buffered vs Unbuffered Channels:** What is the difference between a buffered and an unbuffered channel in Go? When might you use a buffered channel? [7]
- **Select Statement:** How does the `select` statement work in Go? Provide an example of using `select` to await multiple channel operations. What happens if multiple channels are ready at the same time? (How does Go choose a case to execute?) [8]
- **Mutexes:** What is a `sync.Mutex` and how do you use it to protect shared data in Go? Compare using a mutex to using channels for coordinating access to a shared resource – when might you choose one over the other?
- **Atomic Operations:** What are atomic operations in Go (from the `sync/atomic` package)? Give an example of using an atomic operation and explain when you would use atomics instead of a mutex.
- **GOMAXPROCS:** What is `GOMAXPROCS`? How does changing `GOMAXPROCS` affect the execution of goroutines in a multi-core system?

Advanced

- **Scheduler Internals (G, M, P):** Explain how goroutines are scheduled onto OS threads in Go's runtime. What are the roles of G, M, and P in the scheduler, and how do they work together to execute goroutines? [6]
- **Locks vs Channels vs Atomics:** Go provides several concurrency primitives (channels, mutexes, atomic operations). Compare these approaches – for example, when is communicating over a channel preferable to using a `sync.Mutex`? When would an atomic operation be most appropriate?
- **RWMutex:** What is a `sync.RWMutex` (read-write mutex) and how does it differ from a normal mutex? When would you use an RWMutex instead of a plain mutex for protecting shared data?
- **Select Fairness:** If you have a `select` with multiple ready channels and no `default` case, how does Go decide which case to run? (Discuss fairness/randomness in the Go scheduler's selection of channels.)
- **Deadlocks and Detection:** What happens if all goroutines in a Go program are blocked (deadlocked)? How does the Go runtime detect deadlock, and what error does it report in that situation?

4. Interfaces and Type System

Basic

- **Interface Concept:** What is an interface in Go? How do you declare an interface type, and how does a type satisfy (implement) an interface?
- **Implicit Implementation:** How does Go's implicit interface implementation differ from languages like Java or C#? (Discuss how any type with the required methods satisfies the interface, without an explicit `implements` clause.)
- **Empty Interface:** What is the empty interface (`interface{}`) and what are common use cases for it? Why is it often referred to when talking about Go's lack of generics prior to Go 1.18?
- **Type Assertion:** What is a type assertion in Go? Give an example of using `x.(T)` on an interface value and handling the case where the interface does not hold the desired concrete type.
- **Standard Interfaces:** Give an example of a common interface from Go's standard library (for example, `io.Writer` or `fmt.Stringer`) and a type that implements it. How does this demonstrate Go's interface-oriented design?

Intermediate

- **Type Switch:** How do you perform a type switch in Go? Provide an example of using a `switch v := x.(type) {...}` construct to handle multiple possible concrete types stored in an interface.
- **Pointer vs Value Receivers:** If a method has a pointer receiver, can you call it on a value instance of that type (and vice versa)? How does the method set of a type versus *Type affect whether the type satisfies an interface?
- **Method Sets and Interfaces:** What is a method set in Go? Explain how the method set of a type or pointer determines whether it implements a given interface.
- **Type Alias vs Defined Type:** What is the difference between a type definition (`type MyInt int`) and a type alias (`type MyInt = int`)? In what situations would you use one versus the other?
- **Compile-Time Interface Check:** How can you verify at compile time that a type implements a particular interface? (Hint: a common pattern is assigning a nil pointer of the type to a variable of the interface type.)

Advanced

- **Nil Interface vs Nil Value:** When is an interface value equal to `nil`? Explain why an interface value that holds a nil pointer (or nil concrete value) can still be non-nil, and how this can lead to surprises in nil checks [9].
- **Unexported Interface Methods (Sealed Interface):** Go interfaces are implicitly satisfied. Is there a way to design an interface such that only certain types can implement it (for example, to create a "closed" or sealed set of implementors)? (Hint: use an unexported method in the interface.)
- **Non-Copyable Types:** How can you make a custom struct type non-copyable (to prevent shallow copies)? (One approach is to embed a zero-sized field with an unexported `Lock()` method, such as from `sync.NoCopy`, so that `go vet` can warn on copies [10] [11].)
- **Embedding Conflicts:** What happens if you embed two struct types into another struct and those embedded structs have a method with the same name? How would you call one of those methods from the containing struct, or how would you resolve the conflict?

- **Reflection and Type Information:** Using the `reflect` package, how can you obtain the type and value of an interface variable at runtime? Provide a brief example. Also, why should reflection generally be avoided in everyday code?

5. Generics (Go 1.18+)

Basic

- **Generics Introduction:** Go 1.18 introduced generics (type parameters) into the language [12]. What are generics in Go, and what problem do they solve?
- **Generic Function Syntax:** How do you define a generic function in Go? For example, show the syntax of a function that takes a type parameter `[T any]` and explain the meaning of the `any` constraint.
- **Generic Type Example:** How would you declare a generic type (e.g., a slice or list type) in Go? Give a simple example of a generic struct or interface (if applicable) with a type parameter.
- **"any" vs interface{}:** What is the `any` identifier in Go generics? How is `any` related to the empty interface type, and why was `any` introduced? [13] [14]
- **Basic Use Case:** Provide a basic example of using generics – for instance, a function `PrintSlice` that can accept a slice of any type and print its elements. How would you call this function with different types?

Intermediate

- **Constraints:** What is a *constraint* in the context of Go generics? How do you restrict a type parameter to types that have certain properties or operations?
- **Comparable Constraint:** What does the built-in `comparable` constraint signify? Give an example of a generic function or type that requires its type parameter to be comparable (e.g., usable as a map key) [15].
- **Numeric Constraints:** How can you write a generic function that only works for numeric types (e.g., an addition or min function)? Consider the use of the `constraints` package or interface unions like `interface{ ~int|~float64|... }`.
- **Type Inference:** Explain how type inference works for generics. For example, if you have a generic function `func MapSlice[T, U any](in []T, f func(T) U) []U`, do you always need to explicitly specify the type parameters when calling it?
- **Generics vs Empty Interface:** Prior to generics, Go developers often used `interface{}` to write flexible functions (along with type assertions). In what situations are generics preferred over using empty interfaces and type assertions? Are there cases where using an empty interface is still more appropriate?

Advanced

- **Type Sets (~ and |):** Go's type parameters can use *union of types* and *underlying type* constraints. Explain the usage of the `~` operator and the `|` operator in type constraints, with an example (for instance, `interface{ ~int | ~float64 }`). How do these allow a form of ad-hoc polymorphism over a set of types? [16] [17]
- **New Built-ins:** Go 1.21 added new built-in functions `min`, `max`, and `clear` to work with generic types [18]. What does each of these functions do? (Explain `min(a, b)` and `max(a, b)` for ordered types, and `clear(x)` for maps and slices.)
- **Generic Standard Library:** Name some of the new standard library packages introduced to take advantage of generics (for example, the `slices`, `maps`, or `cmp` packages in Go 1.21 [19]). Pick one and describe the kind of generic functionality it provides.

- **Generics Performance:** How are generics implemented under the hood in Go (e.g., via dictionaries and code instantiation at compile time)? Do generics incur any runtime performance penalty compared to writing type-specific code by hand? Discuss the impact on binary size and compile time.
- **Limitations of Generics:** Even with generics, there are some things you still cannot do in Go. Can you give an example of a limitation of Go's generics? (For instance, you cannot perform arithmetic on a generic type without constraining it to a builtin numeric interface, you cannot convert a `[]T` to `[]interface{}` directly, etc.)

6. Error Handling and Debugging

Basic

- **Error vs Exception:** How does Go handle errors, and how is this approach different from languages that use exceptions? Describe the idiomatic Go error-handling pattern using multiple return values.
- **The `error` Type:** What is the built-in `error` type in Go? How do you create an error value? (For example, using `errors.New` or `fmt.Errorf`.)
- **Panic:** What is a `panic` in Go? In what situations is it appropriate to use `panic`? Contrast panicking with returning an error (for example, panics for unrecoverable conditions such as internal invariants or initialization failures).
- **Recover:** What is the role of `recover` in Go? How do you use `recover` to regain control after a panic, and where must `recover` be called to successfully intercept a panic?
- **Deferring for Cleanup:** Give an example of using `defer` to ensure some cleanup or resource release happens even if a function returns an error or encounters a panic (for example, closing a file or releasing a lock).

Intermediate

- **Error Wrapping:** What is *error wrapping* in Go? How do the `fmt.Errorf("%w", err)`, `errors.Is`, and `errors.As` functions work together to create and check wrapped errors?
- **Sentinel Errors:** What is a *sentinel error*? Give an example (such as `io.EOF`). Why can relying on sentinel errors be problematic in large applications or libraries?
- **Panic vs os.Exit:** What is the difference between calling `panic` and calling `os.Exit` to terminate a program? In terms of defers and cleanup, how does a panic+recover differ from an os.Exit?
- **Race Detector:** What tool can you use to detect race conditions in a Go program at runtime? How do you enable it, and what kind of issues can it find? (Discuss `-race` flag for `go run` / `go test` and data race detection.)
- **Debugging Tools:** What facilities or tools does Go provide for debugging and troubleshooting? (For example, the built-in `runtime/debug` package, using a debugger like **Delve**, or printing stack traces with `debug.PrintStack()` in a deferred recovery.)

Advanced

- **Multiple Error Join:** Go 1.20 introduced `errors.Join` to combine multiple errors into one [20]. What is the purpose of `errors.Join` and how do you retrieve the individual errors from a joined error?
- **Profiling with pprof:** How would you go about profiling a Go program to investigate CPU or memory performance issues? Describe the use of the `net/http/pprof` package or the `go`

`tool pprof` with a CPU profile, and what kind of output it provides for debugging performance.
- **Fuzz Testing:** Go 1.18 added support for fuzz testing. What is fuzz testing and how do you write a fuzz test in Go (e.g., using `func FuzzXxx(f *testing.F)`) to discover edge cases or crashes? When would you use fuzz tests during debugging?
- **Stack Traces on Error:** By default, an error does not include a stack trace. How might you augment errors with stack traces or additional context in Go? (Discuss approaches like third-party packages that capture stack traces, or manually using `runtime.Callers` in a custom error type.)
- **Go Debugging Internals:** The Go runtime provides some environmental variables for debugging internals (like `GODEBUG` for GC and scheduler traces). Give an example of using a Go runtime debug option to diagnose issues (for instance, `GODEBUG=gctrace=1` to observe garbage collector activity).

7. Testing and Benchmarking

Basic

- **Writing a Test:** How do you write a basic unit test in Go? Describe the naming convention for test files and test functions, and show a simple example of a test function using `t *testing.T`.
- **Running Tests:** How do you run tests for a Go package? What command and options can be used (`go test`, `-v` for verbose, etc.)?
- **Test Failure:** In a test, what is the difference between `t.Errorf` / `t.Fail` and `t.Fatal` / `t.FailNow` in the `testing` package? When would you use one versus the other?
- **Test Organization:** What is the recommended way to structure test code in terms of files and package naming? (Discuss using `<pkg>_test.go` files and possibly using an external test package for black-box testing.)
- **Table-Driven Tests:** What is a table-driven test in Go? Why are table-driven tests a common idiom for testing multiple scenarios, and how would you implement one?

Intermediate

- **Subtests:** What are *subtests* in Go's testing framework? How do you use `t.Run(name, func(t *testing.T){ ... })` to create subtests, and what are some benefits of subtests?
- **Parallel Tests:** How can you run tests in parallel in Go? Explain the use of `t.Parallel()` within a test function and when running tests in parallel is useful (and any caveats).
- **Benchmarks:** How do you write a benchmark in Go? What does a basic benchmark function look like (function `BenchmarkXxx(b *testing.B)`), and how do you run benchmarks using the `go test` command?
- **Benchmark Metrics:** When you run benchmarks (e.g. with `go test -bench . -benchmem`), what kind of metrics do you get in the output? Explain `ns/op`, `MB/s`, and allocs in the benchmark result and how they guide performance tuning.
- **Coverage:** How can you measure test coverage in Go? What command would you use to get a coverage percentage, and how can you generate a coverage report to see which lines of code are not covered by tests?

Advanced

- **Fuzz Tests:** How do you write and run a fuzz test in Go (available since Go 1.18)? Provide a simple example of a fuzz target function and explain how you would execute it with `go test -fuzz`. In what situations is fuzz testing especially useful?
- **Testing for Panics:** How can you test that a function properly triggers a panic under certain conditions? Describe a technique for writing a test that expects a panic (using `defer` + `recover`, or using the `require.Panics` assertion from testify, etc.).
- **Benchmark Optimization:** If a benchmark shows that a function allocates too many objects (allocs/op) or is too slow, what approaches might you take to optimize it? (For instance, avoiding unnecessary allocations, using preallocated buffers, inlining critical code, etc.)
- **Profile-Guided Benchmarking:** How can you incorporate profiling into your tests or benchmarks? (E.g., using `-cpuprofile` or `-memprofile` flags with `go test` to generate profiles.) Once you have a profile, how do you analyze it to find bottlenecks?
- **Testing Best Practices:** What are some best practices for writing maintainable tests in Go? (Consider factors like test independence, avoiding flaky tests (maybe by controlling randomness or time), using test helper functions, and clear naming and error messages in tests.)

8. Build and Tooling (Modules, Build, CI/CD)

Basic

- **Go Build/Run/Install:** What is the difference between `go build`, `go run`, and `go install`? When would you use each one?
- **Go Modules:** What is a Go module and what file identifies a module in your project? How do you create a new module for a project?
- **go.mod Contents:** Explain the purpose of the `go.mod` file. What kind of information is stored in `go.mod` and how does the Go tool use it?
- **Adding Dependencies:** How do you add an external dependency to a Go module? For example, if you want to use a package from GitHub, what steps do you take (e.g. import it in code and run `go mod tidy` or use `go get`)?
- **gofmt and go vet:** What do the tools `gofmt` and `go vet` do? Why is it strongly recommended to run `gofmt` on your code? (Discuss code formatting consistency and catching common mistakes.)

Intermediate

- **GOPATH vs Modules:** What were GOPATH workspaces and how has Go Modules changed the way we manage dependencies? What are `GOROOT` and `GOPATH`, and do you need to set them when using modules?
- **Versioning and SemVer:** How do Go modules handle versioning of dependencies? For example, how would you upgrade to a new major version of a dependency (v2+), and what is *semantic import versioning* (the `/v2` suffix in module paths)?
- **go get and Tidy:** In the module context, what is the role of `go get`? How do you upgrade or downgrade a dependency's version using the Go tooling? What does `go mod tidy` do?
- **Vendoring:** What is vendoring in Go and how do you vendor dependencies using modules? In a module-enabled project, how do you enable module vendoring and why might you use it?
- **Build Tags:** What are build tags (or `//go:build` directives) in Go? Give an example of how you would use a build tag to compile certain files only on a specific OS or architecture (or to include/exclude debug code).

Advanced

- **Workspaces (go.work):** Go 1.18 introduced the concept of workspaces with a `go.work` file for working with multiple modules. What is a Go workspace and when would you use a `go.work` file? Describe how you might set up a workspace to develop two modules simultaneously without using replace directives [21] [22].
- **Profile-Guided Optimization (PGO):** Go 1.20/1.21 added Profile-Guided Optimization support [23]. What is PGO and how can it improve performance? Outline the steps to build a Go program with PGO (generating a profile and using it to build).
- **Cross-Compilation:** How do you cross-compile a Go program for a different OS or architecture? For example, what environment variables or `go build` flags would you set to build a Linux binary from a Windows or Mac machine (or build for ARM on an x86 machine)?
- **Module Proxy:** By default, the Go module system downloads modules from the Go proxy. What is the purpose of the module proxy (`proxy.golang.org`)? And how can you disable it or use a different proxy (e.g., by setting the `GOPROXY` environment variable)?
- **Continuous Integration (CI):** What are some considerations for using Go in a CI/CD pipeline? (For instance, caching module downloads by enabling the module cache, running `go test` and `go vet` as part of builds, using `go install` to install tools, etc.)

9. Performance and Optimization

Basic

- **Garbage Collection:** What is garbage collection (GC), and how does Go's garbage collector help with memory management? What trade-offs come with using a garbage-collected language in terms of performance (e.g., GC pauses, but ease of use)?
- **Allocation Costs:** Why is it generally beneficial for performance to minimize unnecessary memory allocations in Go? Give an example of how you might reduce allocations in a hot code path (for instance, by reusing buffers).
- **Big-O Complexity:** Even though it's not Go-specific, understanding algorithm complexity is important. What is the time complexity of looking up an element in a slice versus a map in Go? (Discuss linear scan O(n) for slices and average O(1) for map lookups.)
- **Value vs Pointer Performance:** How can choosing between a value type and a pointer type impact performance? (For example, copying a large struct versus passing a pointer to it.) When might you deliberately use a pointer to avoid copying, and when might avoiding pointers (to enable stack allocation or reduce GC pressure) be better?
- **Concurrency Overhead:** Do goroutines come for free? Explain the runtime overhead of creating and scheduling goroutines. Approximately how small is a goroutine's initial stack, and why does that make having many goroutines feasible?

Intermediate

- **Escape Analysis:** What is escape analysis in the Go compiler? How does it decide whether to allocate a variable on the stack or heap during compilation, and why is heap allocation generally "worse" for performance?
- **sync.Pool:** What is `sync.Pool` and how can it be used to improve performance? Give an example of using a `sync.Pool` to reuse objects and reduce GC pressure [24]. What are some caveats of using a pool (e.g., objects in the pool may be garbage-collected, pool is best for transient objects)?
- **GOMAXPROCS Tuning:** In what scenarios might you tune `runtime.GOMAXPROCS` to improve performance? For example, if you set GOMAXPROCS to 1 on a multicore machine, what impact

does that have on CPU parallelism? Conversely, what is the effect of setting it higher than the number of CPU cores?
- **Benchmarking for Allocations:** If you suspect a function is causing too many allocations, how could you verify this using benchmarks? (Hint: use `go test -bench` with the `-benchmem` flag to see allocs/op and bytes/op.) What do these metrics tell you, and how would you act on them?
- **Profiling Tools:** Describe how you would use Go's profiling tools to investigate a performance problem. For example, how would you enable CPU profiling or memory profiling in a running program or test, and what kind of information would a pprof report give you (flame graphs, hottest functions, allocation hotspots, etc.)?

Advanced

- **GC Internals:** Explain the basics of Go's garbage collection algorithm (mark-and-sweep, mostly concurrent since Go 1.5). What does it mean that Go's GC is *non-generational* and what impact might that have on programs with a mix of short-lived and long-lived objects?
- **Unsafe Optimizations:** Sometimes developers use `unsafe` or low-level tricks for performance. For example, how can `unsafe.Pointer` be used to convert a `[]byte` to a `string` without copying, and why must this be done very carefully?
- **Memory Leaks in Go:** Even with garbage collection, it's possible to have memory leaks (or uncontrolled memory growth) in Go. Describe a scenario that could cause a "memory leak" in Go (for instance, leftover references in a long-lived slice or map, goroutine leaks, etc.), and how you would detect and remedy it.
- **Goroutine Stack Size:** Goroutines start with a small stack (on the order of a few kilobytes) and grow as needed. How does this stack growth strategy benefit performance? Have you ever had to tune or monitor goroutine stack usage (for example, using `runtime.Stack` or `debug.SetMaxStack`)?
- **CAP Theorem Trade-offs:** (This is more system design, but performance-related.) In a distributed Go application, if you need high availability, you might choose eventual consistency over strong consistency. How do concepts like eventual consistency, back-pressure, and rate-limiting come into play when optimizing a Go service under high load?

10. Goroutines and Channel Patterns

Basic

- **Stopping Goroutines:** Suppose you start a goroutine that runs an infinite loop or a long-running task. How can you signal that goroutine to stop gracefully? Describe a pattern for cancellation (for example, sending a signal on a channel or using a `context.Context`).
- **Worker Pool:** What is a worker pool pattern? How would you implement a basic worker pool in Go using goroutines and channels? (For example, N worker goroutines reading tasks from a jobs channel and writing results to a results channel.)
- **Producer-Consumer:** Explain the producer-consumer pattern in the context of Go. How would a producer goroutine communicate with a consumer goroutine? Provide a simple example using a channel to send data from producer to consumer.
- **Graceful Shutdown Pattern:** How can you ensure that when your program is shutting down (for instance, on interrupt), all goroutines complete their work or exit cleanly? (Hint: use a done channel or context to notify goroutines, and maybe a WaitGroup to wait for them.)
- **Periodic Tasks:** How would you implement a periodic task in Go, say something that ticks every second? (Hint: you could use `time.Ticker` in a goroutine, or a loop with `time.Sleep`.)

Intermediate

- **Pipeline Pattern:** What is a pipeline in Go concurrency? Describe how you can have a series of stages (goroutines) where each stage receives data from the previous stage via a channel, processes it, and sends it on to the next stage. What are the benefits of this pattern?
- **Fan-Out / Fan-In:** Explain the **fan-out** and **fan-in** concurrency patterns. How would you fan out work to multiple goroutines (for parallel processing of independent tasks), and then fan in results back to a single channel?
- **Context for Cancellation:** How does the `context.Context` help implement cancellation or timeouts across goroutines? Give an example of launching multiple goroutines that all stop when a context is cancelled or its deadline expires.
- **Select with Timeout:** How can you use the `select` statement to implement a timeout on a channel operation or to perform a non-blocking receive? (For example, using `time.After` to avoid waiting indefinitely.)
- **Semaphore Pattern:** Describe a pattern for limiting the number of goroutines running at the same time (a concurrency semaphore). How could you implement this using a buffered channel or another mechanism?

Advanced

- **sync.Once:** What is `sync.Once` and how can it be used in concurrent code? Give an example of something you might want to initialize only one time even if multiple goroutines attempt it (e.g., lazy initialization of a singleton resource).
- **sync.Cond:** What is a `sync.Cond` (condition variable) in Go, and when would you use it instead of channels? Provide a scenario where `sync.Cond` is useful (for example, coordinating multiple goroutines to wait until a condition is true, such as a buffer becoming non-empty).
- **Broadcast via Channel Close:** Go doesn't have a built-in broadcast channel, but how can closing a channel be used as a broadcast signal to many goroutines? (Explain that any number of goroutines can be waiting on a channel receive, and closing the channel wakes all of them up receiving a zero value.)
- **Throttling (Rate Limiting):** How might you implement rate limiting or throttling of goroutines using channels or other primitives? (One approach: use a ticker to pace work, or a semaphore channel to limit how many events proceed per unit time.)
- **Patterns for Avoiding Leaks:** In long-running systems, goroutine leaks are a common problem. What patterns can you follow to avoid leaking goroutines in pipelines or when using channels? (E.g., ensure that sender goroutines exit when receivers are done, by listening on a done channel or by closing channels to signal completion.)

11. Networking and HTTP

Basic

- **HTTP Server:** How do you start a simple HTTP server in Go using the `net/http` package? Write a snippet that sets up an HTTP handler function and listens on a port.
- **HTTP Client:** How can you make an HTTP GET request in Go? Show a basic example using `http.Get` (or `http.NewRequest` and `http.Client`) to fetch data from a URL and read the response body.
- **Handlers and Routing:** What is an `http.Handler` in Go? Explain the difference (if any) between using `http.HandleFunc` with a function versus implementing the `http.Handler` interface on a custom type.

- **Concurrent Requests:** Is the Go `net/http` server concurrent, or do you need to spawn goroutines for each request? Explain how the server handles incoming requests (each request is handled in its own goroutine).
- **Status Codes and Headers:** How do you set the HTTP status code and headers in a Go HTTP handler? Give an example of setting a 404 status and a custom header in the response.

Intermediate

- **gRPC Basics:** What is gRPC and how do you use it in Go? Describe the process of defining a service with Protocol Buffers and generating Go code from it. What advantages does gRPC have over a typical REST/JSON API?
- **Middleware:** In Go web services, what is a middleware (or wrapper) for HTTP handlers? How would you implement a simple middleware pattern to log requests or handle authentication on top of the `net/http` handlers?
- **Graceful Shutdown (HTTP):** How can you implement graceful shutdown of an HTTP server in Go (so that it stops accepting new requests and lets in-flight requests finish before exiting)? (Hint: use `http.Server.Shutdown` with a context to allow a timeout for shutdown.)
- **Context in Handlers:** What is the purpose of the `Context` available via `http.Request.Context()` in a handler? How can it be used to cancel long-running requests if the client disconnects or a timeout is reached?
- **Connection Reuse:** Explain how the `http.Client` in Go manages connections. Why is it usually best to reuse a single `http.Client` (with its default Transport) for multiple requests rather than creating new clients frequently?

Advanced

- **Streaming (HTTP/gRPC):** How would you implement streaming responses in Go? For example, sending a large file or continuously pushing data over an HTTP connection (server-sent events, long polling, or WebSockets). In gRPC, how do you implement server-side or bidirectional streaming RPCs in Go?
- **Performance Tuning HTTP:** What are some ways to tune or improve the performance of a high-traffic HTTP server in Go? (Consider settings like increasing `ListenAndServe` backlog, using HTTP/2 which is on by default for TLS, leveraging sync.Pool for buffers, etc.)
- **Response Body Management:** When making HTTP requests with `http.Client`, what must you remember to do with the response body? (Answer: always close it, typically via `defer resp.Body.Close()`, to avoid leaking connections) [25]. What happens if you don't close the response body?
- **Security (TLS):** How do you serve HTTPS in Go using the `net/http` package? (Discuss using `ListenAndServeTLS` or configuring a `http.Server` with TLS certificates.) Additionally, how would you configure client-side TLS in the `http.Client` (e.g., custom transport with Root CAs, client cert)?
- **Advanced Debugging (HTTP):** If an HTTP server in Go is behaving unexpectedly under load (e.g., slow responses, connection drops), what tools or techniques could you use to debug it? (Possibilities: pprof profiling for hotspots, `httputil` trace, logging with latency, using `curl` or `hey` for load testing, examining `GODEBUG=http2debug=2` for HTTP/2 issues, etc.)

12. System Design with Go

Basic

- **Monolith vs Microservices:** What is a microservices architecture, and how does it differ from a monolithic architecture? What are some reasons a team might choose to build microservices, and why is Go a good fit for microservices?
- **Go in Microservices:** Go is often used for cloud services and microservices. What features of Go make it well-suited for building microservices (for example, fast startup, efficient concurrency for handling many requests, small container images, etc.)?
- **Event-Driven Architecture:** What is an event-driven architecture? In a system design context, explain how services might communicate via events (e.g., using a message broker). How could Go programs publish or subscribe to events (what libraries or techniques might be used)?
- **JSON and APIs:** How do Go services typically encode data for communication? Give an example of a Go service exposing a JSON-based REST API (using `encoding/json` to marshal data to HTTP response). Why is JSON a common choice for service communication?
- **Stateless vs Stateful Services:** What does it mean for a Go service to be stateless? Why are stateless services easier to scale horizontally? (For example, no in-memory sessions – each request can go to any instance.)

Intermediate

- **Service Communication:** What are common ways for microservices to communicate with each other? Compare using HTTP/REST, gRPC, and message queues (asynchronous messaging). How does Go support each of these (standard library or third-party libs)?
- **Distributed Transactions:** In a microservices environment, a single operation may span multiple services (each with its own database). What is the Saga pattern for handling distributed transactions and ensuring consistency across services? How might you implement a Saga in Go (e.g., orchestrator service or choreography using events) [26] ?
- **Circuit Breaker:** What is a circuit breaker pattern in system design? Why might you need a circuit breaker when calling external services, and how could you implement or use one in a Go service (consider using a library or implementing a simple state machine to fail fast)?
- **Service Discovery:** In a microservice architecture, how do services find each other (service discovery)? If you were designing a Go microservice system, what tools or techniques might you use for service discovery (for example, DNS, Consul, etc.)?
- **Messaging and Go:** If you use a message broker (like NATS, RabbitMQ, or Kafka) for event-driven communication, how would a Go service publish and subscribe to messages? (Mention Go client libraries for these systems, and how you might structure goroutines to handle incoming messages.)

Advanced

- **CAP Theorem:** Explain the CAP theorem (Consistency, Availability, Partition Tolerance) in the context of distributed systems. Given a network partition, a system has to choose between consistency and availability. How might this influence the design of a Go-based microservice (for example, choosing eventual consistency and availability in an AP system like many Golang-based NoSQL stores)?
- **Idempotency:** In a distributed system, why is idempotency important for operations (especially when using retries)? How could you ensure an operation is idempotent in a Go microservice – for example, assigning unique IDs to requests or keeping track of processed messages to avoid duplicate processing?

- **Distributed Locking/Leader Election:** If you needed a coordination mechanism like a distributed lock or leader election between multiple Go service instances, what technologies could you use? (For example, using etcd or Consul with Go client libraries, or relying on cloud services.) How would leader election improve certain system workflows?
- **Distributed Tracing:** What is distributed tracing and why is it useful in a microservices architecture? How would you implement distributed tracing in Go services (mention context propagation of trace IDs, and tools like OpenTelemetry or Jaeger with Go instrumentation)?
- **Go Specific Best Practices in Microservices:** Large-scale Go systems have evolved certain best practices (like using context for cancellations, avoiding goroutine leaks, proper logging, etc.). What are some best practices you would follow when designing a complex Go microservices system to ensure it's maintainable and observable (for instance, structured logging, metrics collection with Prometheus client in Go, graceful shutdown of services, etc.)?

13. Best Practices and Idiomatic Go

Basic

- **Formatting and Linting:** Why is it important to always format your code with `gofmt` (or `go fmt`)? What does it mean that "gofmt is nobody's favorite, yet everybody's" in the Go community? Similarly, what sorts of issues can `go vet` catch?
- **Error Handling Idiom:** Describe the idiomatic way to handle errors in Go. Why do Go functions often return an `error` as the last return value, and how should that be handled at the call site? (Demonstrate the pattern of `if err != nil { return ... }` for propagating errors.)
- **Naming Conventions:** What are some Go naming conventions for packages, variables, and functions? (For example, package names should be short and lowercase, Go avoids stutter in names, exported names use CamelCase starting with a capital letter, interfaces often end with -er if they represent an action, etc.)
- **Idiomatic Looping:** In Go, you typically use `for` for loops (since there's no `while`). Show an idiomatic range loop over a slice or map. Why should you take care when ranging over a map (note: iteration order is random)?
- **"Communicate by sharing memory" Proverb:** One of the Go proverbs is "Don't communicate by sharing memory; share memory by communicating." What does this mean in practice for how you design concurrent programs? (Explain that it encourages using channels to synchronize state instead of mutexes where possible, focusing on message-passing concurrency.)

Intermediate

- **Accept Interfaces, Return Structs:** Explain the guideline "accept interfaces, return concrete types." Why is it often beneficial for a function to accept an interface type as a parameter, but return a specific concrete type (as opposed to returning an interface)?
- **Zero Value Useful:** Many types in Go are designed so that the zero value is immediately usable (e.g., `bytes.Buffer`, `sync.Mutex`, `time.Time`). Why is this a good thing, and can you give an example of designing your own type to have a useful zero value? [8]
- **Global State:** Why is using global variables generally discouraged in Go? How can global state make testing and concurrency more difficult? If you need to share configuration or state, what are more idiomatic ways to do so (e.g., passing dependencies via function arguments or using context)?
- **Context Usage:** It has become a Go best practice that any function that does I/O or calls external services should take a `context.Context` as one of its parameters. Why is this recommended and how does it improve the behavior of libraries and applications?

- **Avoiding Panic:** Why should you generally avoid using `panic` for regular error handling? In what cases is it acceptable or idiomatic to use `panic` in Go programs? (For example, inside a package initialization if something truly unrecoverable occurs, or to indicate programmer errors.)

Advanced

- **Pointer to Interface:** Why is it almost never necessary to have a pointer to an interface type (`*SomeInterface`)? What happens if you pass a pointer to an interface to a function expecting an interface? Explain the concept that an interface value is a tuple of (type, value) and that it already behaves like a pointer/reference.
- **Error String Style:** What are the guidelines for error message strings in Go? (For instance, error messages should not be capitalized and should typically avoid punctuation, so that when they are wrapped or concatenated they form a natural sentence [27].) Why is this guideline in place?
- **Init Function Caution:** When and how are `init()` functions run in Go? Why is overusing `init()` (for complex initialization or program logic) considered a bad practice? What are the downsides of doing significant work in init functions (hint: order of execution, testing difficulties)?
- **Little Copying vs Dependency:** The Go proverb "A little copying is better than a little dependency" encourages what practice? Explain this proverb in your own words and why it might lead to better, more maintainable code (for example, avoiding a huge library import for a small function you could write yourself).
- **Common Mistakes:** What are some common mistakes that Go newcomers might make that are considered non-idiomatic? (Examples: using a for-loop index when range could be used, not checking `err` values, using `print`/`println` instead of the log package, excessively using getters/setters instead of exported fields, creating too many tiny interface types, etc.)
